

# Spying on botnets

Sandor Nemes

# About Me

- Current: Senior Security Researcher at FireEye iSIGHT Intelligence
- Former: Sophos, GE Capital, National Instruments
- What I do: reverse engineering, threat research, coding
- Certs: OSCP, CISSP

*Views expressed here are my own and do not necessarily reflect the opinion of my employer.*

# Introduction

- Cyber threat maps
  - Can look really cool
  - But very limited practical use
- Data sources
  - AV endpoints
  - Network sensors
  - DNS data
  - C2 sinkholes
  - **Bot emulators**

- Other than building awesome looking maps, bot emulators can be used to produce some really useful threat intelligence data for tracking threats and threat actors behind them

# Botnets and bots

- Just a quick recap for those who don't do this as their daily job:
  - Private network of computers
  - Infected with malware
  - Controlled as a group
  - Without the consent of the owner
- Botnet architectures:
  - Client-server – uses one or more Command and Control (C2) servers
  - Peer-to-peer (P2P) – clients directly communicate with each other to relay commands
- Malware family examples:
  - Financial malware (Zeus, Emotet, Ursnif/Gozi/ISFB/Dreambot, Trickbot) – forms botnets
  - Ransomware – does not maintain a persistent control channel, thus does not form botnets

# Botnets and bots

- Zombie computers of the botnet are controlled by the botnet operator via a web-based panel

# How is it possible to extract threat intelligence data from botnets?

- Becoming part of a botnet begins with a malware infection
  - Having a malware sample set or a sample feed is a good start
- Data we are interested in:
  - Information on threat actors
  - Information about targets
- High level steps:

# Identifying the malware family

- Looking at some detections on VirusTotal shows this is far from trivial:

HEUR:Trojan.Win32.Generic	! Spyware:FormBook
malware (ai score=88)	! Packed-YP!B5D681D484DD
BehavesLike.Win32.Fareit.gm	! Trojan:Win32/Dynamer!rfn
Trojan.Win32.Zbot.ekyzrl	! Trj/GdSda.A
Win32/Trojan.Dropper.369	! Spyware.Zbot!816B (TFE:4:x9CjJoel4CL)
static engine - malicious	! Ma/Fareit/B-M

- Challenges:
  - Executable packers/crypters
  - Packer/crypter reuse between families
  - Malware downloaders can confuse behavior based detections

# Extracting malware configuration

- Dynamic malware analysis systems / sandboxes come to the rescue
- Extracting approaches:
  - Process memory dumps
    - Results in many smaller memory dumps
    - Mostly event driven: freeing memory, process termination, first network event
    - If the malware sanitizes the memory after using it then it does not work well
  - VM memory dumps
    - Results in one huge memory dump
    - If malware does not execute properly (e.g. crashes) then it does not work
    - Allows for carving the configuration out using memory forensic tools, e.g. Volatility plugins

# Extracting malware configuration

- Data that we can get:
  - Botnet ID – to track threat actors
  - Version number – to track development
  - Encryption keys – to decrypt traffic
  - C2 servers – indicator of compromise

- Successful extraction also confirms the family

- Extractor scripts break easily with malware family updates

- What else can we do – what can we use the C2 servers for?

# Emulating bot communication

- Emulate the networking parts of the bot with a script
  - Just to clarify: this is NOT emulation as in “CPU emulation”, just the communication is emulated
  - We pretend to be an infected machine and we become part of the botnet
- Various levels of complexity based on the family and protocol
  - HTTP – just need to figure out the GET/POST parameters and the traffic encryption/decryption
  - For custom binary protocols this is much harder
- Data that can be seen from the server responses
  - Commands
  - Web injects
  - Configuration updates (including C2 server updates)
  - New malware samples

# Web injects

```
"injects": [
{
    "set_url_1": [
        "http*://*acc*desjardins.com*"
    ],
    "data_before": "<html*<body*>",
    "inject_flags": 1,
    "data_inject": "<div id=\"_brows.cap\" style=\"position:fixed;top:0px;left:0px;width:100%;height:100%;background-color:black;color:white;font-size:12px;z-index:9999;>"
},
{
    "set_url_1": [
        "https*://*bmo.com/onlinebanking/*"
    ],
    "data_before": "if (self == top) {",
    "data_inject": "document.documentElement.style.display = 'block';",
    "inject_flags": 1,
    "data_after": "} </script>"
},
{
    "set_url_1": [
```

# Emulating bot communication

- Challenges:

- IP addresses / exit nodes
- Malicious commands
- Have to provide fake user data
  - System information
  - Task/window list
  - List of installed applications

- Screenshots

- Silently skip, and don't answer
- Send black images of a certain resolution
- Generate relatively credible screenshots
- Example: Emotet – does not give you data, until you provide some data
- Constantly changing families – emulators break silently

```

```

# Takeaways

- Information extracted from malware samples can be used to emulate communication
- Emulating the bot communication gives you data that can be used to track threat actors behind these botnets
- This information can be really valuable for banks and financial institutions who are usually the targets of these attacks
- Security teams can use this information to get a better understanding of how these threat groups operate and how they develop their capabilities
